physical simulation has been used for decades to gain insight into physical phenomena evaluate stability of designs and in computer graphics to reduce artist effort with increasing computational power and algorithmic improvements we have not only been able to simulate phenomena in higher resolution and more complex domains than ever before but to use simulation as a general problem solving tool this thesis explores the use of audiovisual physical simulation techniques in several directions creating better design tools making physical simulation more accessible and using simulation to gain insight into mathematical models and physical processes first we explore the inverse problem of automatically generating an animation that is synchronized to a recorded sound our main insight consists of sampling a large number of rigid body simulations and treating them as a contact event graph paths in this graph correspond to different animations we show how to efficiently search this graph to find plausible animations synchronized with an input sound this provides a new way

to design and control animations while taking advantage of the fidelity of real sounds which can be difficult to capture with physically based sound synthesis second we examine one way to make physical simulation easier to use modal sound synthesis for rigid objects has seen widespread success due to the ability to precompute vibration modes and radiation fields however its speed comes at a cost namely the large amount of memory required to store the mode shapes we demonstrate how to significantly compress the modes by fitting a moving least squares approximation to them the approximation error is set to take advantage of human perception and we also exploit object symmetry to achieve higher compression finally we explore using physical simulation to synthesize water sounds which are mainly caused by bubble volume vibrations we introduce a method to calculate the frequency of bubble vibrations showing how to accurately take the bubble's size shape and position into account in addition to generating compelling animations this helps evaluate the quality of current bubble forcing and damping models and will hopefully provide a reference to judge future approximations by

realistic computer generated images and simulations require complex models to properly capture the many subtle behaviors of each physical phenomenon the mathematical equations underlying these models are complicated and cannot be solved analytically numerical procedures must thus be used to obtain approximate solutions these procedures are often iterative algorithms where an initial guess is progressively improved to converge to a desired solution iterative

methods are a convenient and efficient way to compute solutions to complex systems and are at the core of most modern simulation methods in this thesis by publication we present three papers where iterative algorithms play a major role in a simulation or rendering method first we propose a method to improve the visual quality of fluid simulations by creating a high resolution surface representation around an input fluid simulation stabilized with iterative methods we introduce additional details atop of the simulation second we describe a method to compute fluid simulations using model reduction we design a novel vector field basis to represent fluid velocity creating a method specifically tailored to improve all iterative components of the simulation finally we present an algorithm to compute high quality images for multifocal displays in a virtual reality context displaying images on multiple display layers incurs significant additional costs but we formulate the image decomposition problem so as to allow an efficient solution using a simple iterative algorithm

digital human characters are a mainstay of video games film and interactive computer graphics applications however animating hands remains a challenging aspect of human character animation posing the hand involves coordinating many degrees of freedom synthesizing a plausible grasp requires careful placement of contacts and realistic rendering must account for intricate colour and texture variations traditional solutions to these problems require significant manual effort by skilled artists it is therefore of great interest to computer animation researchers to develop fast and automatic methods for animating hands this thesis presents methods for improving the realism of hands in real time physics based virtual environments we begin by presenting a framework for skilled motion synthesis wherein reinforcement learning and non linear continuous optimization are used to generate controllers for single handed re orientation tasks a mid level multiphase approach breaks the problem into three parts providing an appropriate control strategy for each phase and resulting in cyclic finger motions that accomplish the task the exact trajectory is never specified as the task goals are concerned with the final orientation and position of the object offline simulations are used to learn controller parameters but the resulting control policy is suitable for real time applications we then describe a method for the simulation of compliant articulated structures using an approximate model that focuses on plausible endpoint behaviour the approach is suitable for simulating physics based characters under static proportional derivative control and stiff kinematic structures like robotic grippers the computation time of the dynamical simulation is reduced by an order of magnitude and faster than real time frame rates are easily achieved additionally the state of internal bodies is computed independently and in a parallel fashion we also demonstrate an approach for synthesizing colour variation in fingers due to physical

interaction with objects a data driven model relates contact information to visible colour changes for the fingernail and surrounding tissue on the back of the fingertip the model construction uses the space of hemoglobin concentrations as opposed to an rgb colour space which permits transferability across different fingers and different people principal component analysis pca on the sample images results in a compact model enabling efficient implementation as a fragment shader program finally we introduce a system for capturing grasping and dexterous interactions with real world objects a novel sensor ensemble collects information about joint motion and pressure distributions for the hand and the data is used to design grasping controllers for a physics based climbing simulation additionally we speculate on how the interaction data can be used to derive future control strategies in physics based animation combining interaction data with physical models is a promising approach for skilled motion synthesis involving hands

in general more than one simulation model can be created to analyze and design engineering systems uncertainty is inevitably involved in selecting a single best approximating model from among a set of simulation models uncertainty in model selection called model form uncertainty in the present research cannot be ignored especially when the differences between the predictions by plausible models are significant also each simulation model involves uncertainty in its input parameters and unknown errors in its predictions of system responses a methodology is developed to quantify model form uncertainty using the differences between experimental data measured from an engineering system and model predictions of the data which may involve parametric and or predictive uncertainty under a bayesian statistical framework the proposed methodology is numerically demonstrated with two engineering problems given that model form uncertainty is quantified two model combination techniques called the adjustment factor approach and model averaging are utilized to incorporate model form uncertainty in response prediction by combining predictions by a model set a nonlinear vibration system is used to illustrate the processes for implementing the adjustment factor approach and model averaging the proposed methodology is applied to quantify multiple types of uncertainty associated with the finite element simulation of a laser peening process the adjustment factor approach is utilized to incorporate model form uncertainty alone into the composite prediction of a residual stress field while model averaging is utilized to incorporate parametric uncertainty and predictive uncertainty in addition to model form uncertainty using the composite prediction of the residual stress field a confidence band for the predicted residual stress field is established to indicate the reliability of the composite prediction although the proposed methodology can effectively quantify model form uncertainty given

observed experimental data it does not supply any practical framework for quantifying model form uncertainty depending on expert evidence another methodology is developed to quantify both model form and parametric uncertainty using human expertise under evidence theory which handles imprecise human knowledge more realistically than probability theory the process for implementing the proposed methodology is numerically demonstrated with the nonlinear vibration system problem the laser peening process problem is addressed to examine the applicability of the proposed methodology to large scale physics based simulations
